1 **FIELD EFFECT TRANSISTORS, FIELD EMISSION APPARATUSES,**
2 **THIN FILM TRANSISTORS, AND METHODS OF FORMING FIELD**
3 **EFFECT TRANSISTORS**

4 **TECHNICAL FIELD**

5 The present invention relates to field effect transistors, field
6 emission apparatuses, thin film transistors, and methods of forming field
7 effect transistors.

8 **BACKGROUND OF THE INVENTION**

9 Field effect transistors are well known in the art. Such
10 transistors are utilized in a variety of applications. One exemplary field
11 effect transistor configuration is the thin film transistor. Thin film
12 transistor configurations have been particularly useful in field emission
13 devices, such as field emission displays.

14 In typical arrangements, thin film field effect transistors are
15 formed over an insulative substrate, such as glass. A thin film
16 semiconductive layer is formed over the insulative substrate. An
17 exemplary semiconductive layer comprises amorphous silicon. A gate
18 dielectric layer and gate layer are provided over the thin film layer and
19 patterned using photolithography to form a gate. Conductive regions
20 are formed intrinsically using plasma enhanced chemical vapor deposition
21 (PECVD) with appropriate gas precursors to form the thin film field
22 effect transistor construction.

23 Precise alignment of the gate with the active region of a field
24 effect transistor, including thin film transistor configurations, is desired

1 to ensure proper operation of the device as well as enhance the
2 operational characteristics of the device. There exists a need in the art
3 to provide improved field effect transistor device configurations and
4 methodologies for fabricating such transistor devices for controlling
5 emission.

6 7 SUMMARY OF THE INVENTION

8 The present invention provides field effect transistors, field
9 emission apparatuses, thin film transistors, and methods of forming field
10 effect transistors.

11 According to one aspect of the present invention a field effect
12 transistor includes a semiconductive layer configured to form a channel
13 region. The field effect transistor further includes a pair of spaced
14 conductively doped regions in electrical connection with the channel
15 region of the semiconductive layer and a gate intermediate the
16 semiconductive regions. A gate dielectric layer is provided intermediate
17 the semiconductive layer and the gate, and the gate dielectric layer is
18 configured to align the gate with the channel region of the
19 semiconductive layer.

20 According to some aspects of the present invention, the conductive
21 regions comprise source/drain regions. One of the source/drain regions
22 may be formed to comprise a field emitter providing a field emission
23 apparatus. The field emission apparatus is configured as an active field
24 device in some configurations.

1 In one aspect, chemical-mechanical polishing self-aligns the gate
2 with the channel region. According to another aspect, a field emission
3 device includes a transistor configured to control the emission of
4 electrons from an emitter.

5 Yet another aspect of the present invention provides a method of
6 forming a field effect transistor. The method includes the steps of
7 forming a semiconductive layer having a channel region and forming
8 plural spaced conductively doped regions electrically coupled with the
9 semiconductive layer. This method further provides forming a gate
10 dielectric layer over the semiconductive layer, forming a gate over the
11 gate dielectric layer, and aligning the gate with the channel region using
12 the gate dielectric layer.

13 Other aspects of the present invention are disclosed herein.

14 15 BRIEF DESCRIPTION OF THE DRAWINGS

16 Preferred embodiments of the invention are described below with
17 reference to the following accompanying drawings.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

This disclosure of the invention is submitted in furtherance of the constitutional purposes of the U.S. Patent Laws "to promote the progress of science and useful arts" (Article 1, Section 8).

The present invention discloses transistors and methods of forming transistors. An exemplary transistor of the present invention includes a thin film transistor (TFT) having a semiconductor-on-insulator (SOI) construction. One fabrication method of the present invention for forming a first thin film field effect transistor configuration is described herein with reference to Fig. 1 - Fig. 11. A second thin film field effect transistor configuration according to the present invention is depicted in Fig. 12. Fabrication of another thin film field effect transistor arrangement including a field emitter is described herein with reference to Fig. 13 - Fig. 16. The configuration depicted in Fig. 16 comprises an active switching field emission device. Although the present invention is described with reference to thin film field effect transistors, the invention is not to be limited to such disclosed configurations.

Referring to Fig. 1 and Fig. 2, a segment or fragment 10 of a thin film field effect transistor is illustrated. Segment 10 includes an insulative substrate 12 and a semiconductive layer 14 formed over insulative substrate 12. Exemplary materials for insulative substrate 12 include glass, sapphire or silicon oxide. Semiconductive layer 14 is preferably formed as a thin film semiconductive layer having an

1 approximate height or thickness of 0.2 - 0.5 microns. Thin film
2 semiconductive layer 14 comprises amorphous silicon according to the
3 described embodiment although other materials may be utilized, such as
4 SiC, CdSe, polycrystalline Si, microcrystalline Si, etc.

5 Thin film semiconductive layer 14 is ideally doped to provide
6 increased conductivity. In one embodiment, thin film semiconductive
7 layer 14 is doped with a p-type impurity using intrinsic doping. As
8 described below, thin film conductive layer 14 is configured to form a
9 channel region 15 of a field effect transistor to selectively conduct
10 electrons between adjacent semiconductive regions (shown in Fig. 5).
11 Accordingly, at least a portion of layer 14 is provided intermediate the
12 subsequently formed semiconductive regions.

13 Formation of thin film semiconductive layer 14 comprises providing
14 a semiconductive layer over an upper surface of insulative substrate 12,
15 and subsequently patterning the layer to provide the configuration
16 illustrated in Fig. 1. Conventional photolithography techniques are used
17 in one embodiment to pattern the thin film semiconductive layer. As
18 shown in Fig. 2, the patterned thin film semiconductive layer 14 forms
19 a substantially rectangular shape in the presently described thin film
20 field effect transistor configuration.

21 Referring to Fig. 3, a semiconductive layer 16 is formed over
22 insulative substrate 12 and patterned thin film semiconductive layer 14.
23 Semiconductive layer 16 has an exemplary height or thickness of
24 approximately 1 - 3 microns and is preferably doped to provide

1 increased conductivity. In the described embodiment, semiconductive
2 layer 16 is preferably doped with an n+ type dopant to provide
3 enhanced conductivity. Intrinsic doping using appropriate precursor gases
4 are utilized in the described embodiment to dope layer 16.

5 Referring to Fig. 4, a patterned mask 18 is provided over
6 semiconductive layer 16. Mask 18 permits subsequent processing of
7 segment 10 in accordance with the present invention. In an exemplary
8 embodiment, mask 18 comprises positive photoresist formed by
9 photolithography. Individual portions of mask 18 individually have a
10 length of approximately 10 microns.

11 Referring to Fig. 5 and Fig. 6, portions of semiconductive
12 layer 16 have been removed providing plural semiconductive
13 regions 20, 22. Semiconductive regions 20, 22 correspond to mask 18
14 and may be formed by etching exposed portions of semiconductive
15 layer 16. A largely isotropic silicon wet etch or plasma dry etch is
16 utilized in one embodiment to etch layer 16 and form regions 20, 22.

17 As illustrated, semiconductive regions 20, 22 are formed over and
18 in electrical connection with thin film semiconductive layer 14 and
19 channel region 15 thereof. Channel region 15 generally extends
20 intermediate semiconductive regions 20, 22. Semiconductive
21 regions 20, 22 preferably comprise spaced conductively doped n+
22 regions. In the presently described embodiment, semiconductive
23 regions 20, 22 are formed as mesas.
24

1 Semiconductive regions 20, 22 comprise source/drain regions of a
2 field effect transistor. In typical applications, semiconductive
3 regions 20, 22 comprise a source region and drain region, respectively.

4 Referring to Fig. 7, a gate dielectric layer 30 and gate layer 32
5 are formed over substrate 12, semiconductive layer 14, and
6 semiconductive source/drain regions 20, 22. Exemplary materials for
7 layers 30, 32 include silicon oxide and conductively doped polysilicon,
8 respectively. In the described embodiment, gate layer 32 is doped with
9 an n+ dopant using plasma enhanced chemical vapor deposition
10 (PECVD) techniques. Gate dielectric layer 30 has an exemplary height
11 within the range of approximately 0.1 - 0.4 microns, and gate layer 32
12 has an exemplary thickness of approximately 0.2 - 0.5 microns.
13 Preferably, gate dielectric layer 30 has a uniform thickness.

14 In the illustrated embodiment, layers 30, 32 are provided with a
15 combined thickness "a" which does not exceed the individual heights "b"
16 of semiconductive regions 20, 22. More specifically, semiconductive
17 regions 20, 22 comprise respective upper outermost surfaces 21, 23.
18 Layer 32 includes an upper outermost surface 33 above channel
19 region 15. As referred to herein, upper outermost surfaces refer to
20 surfaces away from or opposite insulative substrate 12 and thin film
21 semiconductive layer 14. Surfaces 21, 23 are provided elevationally
22 higher than surface 33 in the described embodiment. Surfaces 21, 23
23 may be elevationally coincident or below surface 33 in other
24 embodiments.

1 According to the preferred embodiment, channel region 15 has a
2 thickness less than the thickness of layer 32. Accordingly, the height
3 of region 15 and layer 30 have a combined thickness "c" less than a
4 combined thickness "d" comprising layer 30 and layer 32.

5 Referring to Fig. 8 and Fig. 9, portions of gate dielectric
6 layer 30, gate layer 32 and semiconductive regions 20, 22 have been
7 removed. According to the described fabrication method, segment 10
8 is polished to remove portions of regions 20, 22 and layers 30, 32.
9 The polishing comprises chemical-mechanical polishing according to the
10 preferred embodiment. Respective uppermost surfaces or portions of
11 semiconductive regions 20, 22 are removed before removing any portions
12 of gate dielectric layer 30 formed above a subsequently formed gate
13 (having reference numeral 34 in Fig. 8). Polishing of segment 10
14 comprises initially polishing respective uppermost surfaces 21, 23 of
15 source/drain regions 20, 22 before polishing any portions of gate
16 layer 32 comprising surface 33 (surfaces 21, 23 and 33 are shown in
17 Fig. 7) above thin film channel region 15. Surface 33 of gate layer 32
18 tends to act as a stopping position during polishing of fragment 10.

19 A timed etch is used in an alternative fabrication method to
20 remove portions of gate dielectric layer 30, gate layer 32 and
21 semiconductive regions 20, 22.

22 The processing step shown in Fig. 8 provides an isolated gate 34
23 intermediate semiconductive source/drain regions 20, 22. Gate 34 is
24 formed over and operatively proximate channel region 15. More

1 specifically, gate 34 is configured to control current flow intermediate
2 semiconductive regions 20, 22 through channel region 15.

3 The described processing method for forming gate 34 includes
4 removal of portions of gate dielectric layer 30, gate layer 32 and
5 semiconductive regions 20, 22 in a common processing step. Preferably,
6 gate 34 is formed without the use of a mask over gate material which
7 subsequently forms gate 34. In particular, portions of both gate
8 dielectric layer 30 and gate material layer 32 are removed using
9 polishing or etching techniques as previously described without using a
10 mask over the gate material which forms gate 34.

11 Utilization of the described and preferred fabrication method
12 provides a gate 34 which self-aligns with channel region 15, and
13 accomplishes such without any photomasking. Provision of gate
14 dielectric layer 30 having a uniform thickness over thin film
15 semiconductive layer 14, and subsequent removal of portions of gate
16 dielectric layer 30 and gate layer 32 operate to form and align gate 34
17 with channel region 15. The preferred uniform thickness of gate
18 dielectric layer 30 spaces gate 34 equally from semiconductive
19 regions 20, 22 and aligns gate 34 with channel region 15.

20 Still referring to Fig. 8, gate 34 has an upper outermost
21 surface 35 and semiconductive regions 20, 22 have respective upper
22 outermost surfaces 24, 25. In some instances, surface 35 comprises the
23 same surface of gate layer 32 depicted with reference numeral 33 in
24

1 Fig. 7. Alternately, some polishing into layer 32 through surface 33
2 occurs.

3 Surfaces 24, 25 are elevationally lower than surfaces 21, 23 shown
4 in Fig. 7 due to polishing of segment 10 according to the described
5 fabrication method. Gate dielectric layer 30 includes upper outermost
6 surfaces 31 following polishing of segment 10. As illustrated, gate
7 upper outermost surface 35 is substantially elevationally coincident with
8 gate dielectric layer upper outermost surfaces 31 and surfaces 24, 25 of
9 respective semiconductive regions 20, 22.

10 Although such step is not depicted, portions of gate dielectric
11 layer 30 and gate layer 32 located laterally outside of semiconductive
12 regions 20, 22 are preferably removed following the polishing of
13 segment 10 as shown in Fig. 8. A mask is formed over and
14 intermediate semiconductive regions 20, 22 according to one processing
15 method of removing such external material of layers 30, 32. Thereafter,
16 the external portions of layers 30, 32 are etched or otherwise removed
17 to provide the structure shown in Fig. 8.

18 Referring to Fig. 10 and Fig. 11, one configuration of a thin film
19 field effect transistor 38 is shown. Thin film field effect transistor 38
20 formed upon segment 10 includes conductive material formed over
21 gate 34 and source/drain regions 20, 22. The conductive material forms
22 plural source/drain electrodes 40, 42 and a gate electrode 44.
23 Electrodes 40, 42, 44 are utilized to provide electrical connection of
24 respective components of thin film field effect transistor 38 with external

1 circuitry (not illustrated). The conductive material comprises doped
2 silicon or metal in exemplary embodiments.

3 Referring to Fig. 12, another configuration of a thin film field
4 effect transistor is depicted wherein like reference numerals represent
5 like components with any substantial differences indicated by suffix "a".
6 The depicted segment 10a includes an alternative thin film field effect
7 transistor configuration 38a. Thin film field effect transistor 38a of
8 segment 10a includes a conductive layer 17 intermediate insulative
9 substrate 12 and semiconductive layer 14a. Formation of conductive
10 layer 17 provides channel bias of region 15. Semiconductive layer 14a
11 has a reduced thickness compared with the semiconductive layer of
12 previously described transistor configurations. Semiconductive layer 14a
13 is provided over insulative substrate 12 and conductive layer 17.
14 Conductive layer 17 is formed by chemical vapor deposition in one
15 embodiment.

16 Referring to Fig. 13, a segment 10b of a field emission apparatus
17 is illustrated. Segment 10b of Fig. 13 depicts the field emission
18 apparatus at an intermediate processing step corresponding to the
19 processing step of segment 10 illustrated in Fig. 5 and Fig. 6.
20 Segment 10b includes a thin film semiconductive layer 14b having an
21 increased lateral dimension over substrate 12.

22 One of source/drain regions 20, 22a over layer 14b is shaped to
23 form a field emitter 50 in accordance with the presently described
24 embodiment. As illustrated, source/drain region 22 is formed as field

1 emitter 50. Source/drain region 20 comprises a mesa similar to the
2 previously described thin film field effect transistor configurations.
3 Source/drain region 20 could be formed to comprise a field emitter and
4 region 22 could be formed as a mesa in another embodiment.

5 Field emitter 50 can be formed utilizing a mask similar to the
6 depicted mask 18 of Fig. 4 and having a reduced width. Utilization of
7 a narrow mask provides source/drain region 22a with a point which
8 projects outwardly from substrate 12 and thin film semiconductive
9 layer 14b to form field emitter 50. One possible mask for fabricating
10 field emitter 50 comprises a circular mask having a diameter of
11 approximately 1 to 2 microns.

12 In accordance with one fabrication method, source/drain region 22a
13 comprising field emitter 50 is formed by a combination of isotropic and
14 anisotropic etching of semiconductive layer 16 in plasma which contains
15 fluorinated gas, such as NF_3 , in combination with a chlorinated gas,
16 such as Cl_2 , and helium. Such an etching process preferably provides
17 field emitter 50 having an atomically sharp tip. Other fabrication
18 techniques can also be utilized.

19 Referring to Fig. 14, following formation of semiconductive
20 region 22a as field emitter 50, processing of segment 10b occurs in a
21 manner similar to the processing of the thin film field effect transistor
22 previously described. For example, gate dielectric layer 30 and gate
23 layer 32 are formed over semiconductive regions 20, 22a, substrate 12
24 and semiconductive layer 14b. The tip of field emitter 50 is preferably

1 provided elevationally below the surface 33 of gate layer 32 and
2 surface 21 of semiconductive region 20.

3 Referring to Fig. 15, segment 10b has undergone polishing or
4 other processing to remove portions of gate dielectric layer 30, gate
5 layer 32 and semiconductive region 20. Such polishing comprises
6 chemical-mechanical polishing in the described embodiment and ceases
7 prior to any polishing of field emitter 50. As previously described, the
8 removal of portions of layers 30, 32, and region 20 provides a gate 34a
9 aligned with channel region 15 intermediate semiconductive
10 regions 20, 22a.

11 Referring to Fig. 16, segment 10b having a field emission
12 apparatus 60 thereon is illustrated. Field emission apparatus 60
13 comprises a thin film transistor including field emitter 50.

14 Similar to the previously described embodiment, external portions
15 of gate dielectric layer 30 and gate layer 32 are preferably removed
16 following the polishing of segment 10b. However, only the lateral
17 portions of layers 30, 32 adjacent and outwardly of semiconductive
18 region 20 are removed in the preferred embodiment. The external
19 lateral portions of layers 30, 32 adjacent the field emitter 50 are not
20 removed according to one embodiment. More specifically, such lateral
21 portions are utilized to provide an active field emission apparatus 60.
22 The lateral portions provide a gate 34a about field emitter 50.

23 The depicted segment 10b also includes a conductive material
24 comprising electrodes 40, 44a over selected portions of the depicted thin

1 film field emission apparatus 60. The conductive material can comprise
2 doped silicon or metal in exemplary embodiments. Electrodes 40, 44a
3 are utilized to provide electrical connection with respective components
4 of thin film field emission apparatus 60 with external circuitry (not
5 illustrated). Such circuitry is configured in one embodiment to control
6 the operation of field emission apparatus 60. Gate 34a is configured
7 to control current flow intermediate semiconductive region 20 and
8 semiconductive region 22a comprising field emitter 50 responsive to the
9 selective application of a voltage potential via external circuitry (not
10 shown) to gate 34a. Gate 34a also controls the emission of electrons
11 from field emitter 50.

12 Cavity 36 is formed within gate dielectric layer 30 intermediate
13 gate 34a and semiconductive region 20. Cavity 37 is formed within gate
14 dielectric layer 30 adjacent field emitter 50. Cavities 36, 37 are formed
15 by etching in the described embodiment. An etchant is preferably
16 chosen to permit etching of gate dielectric layer 30 with minimal or no
17 etching of gate layer 32 (i.e., selective to gate layer 32) as illustrated.

18 Referring to Fig. 17, a segment 10c having an alternative field
19 emission apparatus 60a thereon is illustrated. Apparatus 60a includes
20 plural emitters 50 as shown. Emitters 50 are formed using the
21 techniques previously described. A gate 34b comprising material of
22 layer 32 is provided about individual emitters 50 similar to the gate 34a
23 of Fig. 16.
24

1 Electrodes 40, 44b comprising a conductive material such as doped
2 silicon or metal are shown over portions of field emission
3 apparatus 60a. Electrodes 40, 44b are coupled with external circuitry
4 (not shown) configured to control the operation of apparatus 60a.
5 Gate 34b is configured to control current flow intermediate region 20
6 and regions 22a comprising field emitters 50. As such, gate 34b
7 controls the emission of electrons from field emitters 50.

8 In compliance with the statute, the invention has been described
9 in language more or less specific as to structural and methodical
10 features. It is to be understood, however, that the invention is not
11 limited to the specific features shown and described, since the means
12 herein disclosed comprise preferred forms of putting the invention into
13 effect. The invention is, therefore, claimed in any of its forms or
14 modifications within the proper scope of the appended claims
15 appropriately interpreted in accordance with the doctrine of equivalents.
